Britt L. Christensen - Misfits (soundtrack) Category:American Academy of Dramatic Arts Category:People from Novato, California

Of the standard methods for measuring blood pressure, those currently in use are classified into two categories: those that measure blood pressure using an inflatable cuff and those that take blood pressure measurements by introducing a pressure-measuring element into a living body via an artery. Blood pressure measurement with a cuff is, in general, performed by measuring a pulse rate and a volume and pressure of a blood-pressure wave that propagates along an artery. Specifically, when a pressure-measuring element inserted into an artery is fixed at a predetermined portion thereof (for example, a wrist or an arm), the inside pressure of the artery is measured as the pressure of the blood-pressure wave that propagates along the artery. The inside pressure of the artery is measured using an oscillometric method, a volume (plethysmographic method), a pulse palpation method (a wall thickness method), or the like. In the case of the oscillometric method, an oscillator that includes a cuff is put around a measurement portion of a body and is tightened; and an amplitude of oscillation of the cuff is measured when the inside pressure of the artery is at a pressure that causes the oscillation (this pressure is defined as "oscillating state blood pressure"). In the case of the volume method, a pressure that causes an artery to change in volume by changing the volume of a segment of the artery is determined, based on the changing blood pressure, and the value thus determined is considered to be the inside pressure of the artery. The volume method has the advantage that it is simple and easy to use, but on the other hand, if the artery tends to have a reduced volume, the result of the measurement tends to be inaccurate. Moreover, for non-invasive measurement, a volume type blood pressure measuring device using radio waves is used. In this case, blood pressure measurement is performed under a state in which a non-contact type (wave transmission type) blood pressure measuring device is brought into contact with the skin of a measurement portion, and radio waves are transmitted, so that the inside pressure of the artery is obtained from an intensity of the received radio waves that have passed through the artery. In the case of the non-contact type blood pressure measuring device, the device needs to be kept in contact with the measurement portion of the body over a long period of

Parathyroid surgery based on ultrasonic technology]. The use of ultrasonic technology during parathyroid surgery, in particular in minimally invasive surgery, is becoming more and more popular. We compared the results of conventional and minimally invasive parathyroidectomy in an extended, prospective study. From March 1st 2007 to June 30th 2010 96 patients underwent surgery in our department. Forty-eight of them were approached by video-endoscopy (group A) and the other 48 by the traditional cervicotomy (group B). All patients were subjected to a preoperative biochemical study: total serum calcium, parathormone and ionised calcium. The surgical procedure is unidirectional based on the removal of all parathyroid tissues after localization. The average

operative time was significantly lower in group A (p
